```

Converting data into factors(categorical) mainly the one which are important to this.

```
\label{eq:nby3} NBy3\\Personal.Loan = as.factor(NBy3\\Personal.Loan) \# converting Personal Loan into categorical data \\NBy3\\Online = as.factor(NBy3\\Online) \# converting Online into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting Credit Card into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting Credit Card into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting Credit Card into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting Credit Card into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting Credit Card into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting Credit Card into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting Credit Card into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting Credit Card into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting Credit Card into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting Credit Card into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting Credit Card into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting Credit Card into categorical data \\NBy3\\CreditCard = as.factor(NBy3\\CreditCard) \# converting CreditCard + as.factor(NBy3\\CreditCard) \# converting Card + as.factor(NBy3\\CreditCard
```

#Data partition 60 % training and 40 % into validation

2

3

4

0

1

1

```
set.seed(64060)
train.index <- sample(row.names(NBy3), 0.6*dim(NBy3)[1]) # 60 % of data into training set
valid.index <- setdiff(row.names(NBy3), train.index) # 40 % into validation set
train.df <- NBy3[train.index,] # assigning the train.index into data frame
valid.df <- NBy3[valid.index,] # assigning the validation index into data frame
train <- NBy3[train.index,] # Making a copy of the data frame train.df
valid = NBy3[train.index,] # Making a copy of the data frame valid.df</pre>
```

A. Create a pivot table for the training data with Online as a column variable, CC as a row variable, and Loan as a secondary row variable. The values inside the table should convey the count. In R use functions melt() and cast(), or function table().

Pivot table For CreditCard , Personal loan as row variables and Online in column.

1 200

0 784

1 85

```
library(reshape2)
melt = melt(train,id=c("CreditCard","Personal.Loan"),variable= "Online")

## Warning: attributes are not identical across measure variables; they will be
## dropped

cast = dcast(melt,CreditCard+Personal.Loan~Online) # dcast is to convert the data in CC , Personal loa

## Aggregation function missing: defaulting to length

cast[,c(1,2,3,14)] # casting column no 14 which credit card and 1 , 2 , 3 column is , personal loa

## CreditCard Personal.Loan ID Online
## 1 0 0 1931 1931
```

200

784

85

B. Consider the task of classifying a customer who owns a bank credit card and is actively using online banking services. Looking at the pivot table, what is the probability that this customer will accept the loan offer? [This is the probability of loan acceptance (Loan = 1) conditional on having a bank credit card (CC = 1) and being an active user of online banking services (Online = 1)].

```
Loan_CC1 <- 77/3000 # 77 is the value for Loan and CC =1 as per pivot table. and 3000 is the total co
Loan_CC1 # which is 26 %.
## [1] 0.02566667
C. Create two separate pivot tables for the training data. One will have Loan (rows) as a function of Online
(columns) and the other will have Loan (rows) as a function of CC.
melt1 = melt(train,id=c("Personal.Loan"), variable = "Online") # Melting Personal loan and Online data i
## Warning: attributes are not identical across measure variables; they will be
## dropped
melt2 = melt(train,id=c("CreditCard"),variable = "Online") # Melting Credicard data with reference to o
## Warning: attributes are not identical across measure variables; they will be
## dropped
cast1 =dcast(melt1,Personal.Loan~Online) # Casting Personal loan and online values
## Aggregation function missing: defaulting to length
cast2=dcast(melt2,CreditCard~Online) # Casting Personal loan and online values
## Aggregation function missing: defaulting to length
Loanonline=cast1[,c(1,13)]
LoanCC = cast2[,c(1,14)]
Loanonline # Indicates personal loan count in reference with online
##

E. Use the quantities computed above to compute the naive Ba1 probability P(Loan = 1 \mid CC = 1, Online)
= 1).
Naive bayes = ((77/(77+198))*(166/(166+109))*(275/(275+2725)))/(((77/(77+198))*(166/(166+109))*(275/(275+109)))/(((77/(77+198)))*(166/(166+109)))*(275/(275+109))/(((77/(77+198)))*(166/(166+109)))*(166/(166+109)))
Naivebayes # 90 % is the probability
## [1] 0.09055758
F. Compare this value with the one obtained from the pivot table in (b). Which is a more accurate estimate?
9.05% are very similar to the 9.7% the difference between the exact method and the naive-baise method is
the exact method would need the the exact same independent variable classifications to predict, where the
naive bayes method does not.

G. Which of the entries in this table are needed for computing P (Loan = $1 \mid CC = 1$, Online = 1)? In R, run naive Bayes on the data. Examine the model output on training data, and find the entry that corresponds to P (Loan = $1 \mid CC = 1$, Online = 1). Compare this to the number you obtained in (E).

Answer:

The naivebayes is the same output we got in the manual calculation method. (.280)(.603)(.09)/(.280.603.09+.29.58.908) = .09 which is the same as the manual calculation.
